

**EXHIBIT B**

**IN THE UNITED STATES DISTRICT COURT  
EASTERN DISTRICT OF TEXAS  
MARSHALL DIVISION**

NORTHEASTERN UNIVERSITY and  
JARG CORP.,

Plaintiffs,

v.

GOOGLE INC.,

Defendant.

Civil Action No. 2:07-CV-486 (TJW)

**Jury Trial Demanded**

**JOINT CLAIM CONSTRUCTION AND PREHEARING STATEMENT**

Pursuant to Eastern District of Texas Patent Rule 4-3, Plaintiffs Northeastern University and Jarg Corporation and Defendant Google Inc. hereby provide their Joint Claim Construction and Prehearing Statement.

**I. AGREED CLAIM CONSTRUCTIONS**

The parties have met and conferred regarding their Rule 4-2 exchange and have agreed to the meaning of certain claim terms, phrases or clauses. These terms, and their agreed meanings, are set forth in Exhibit A (attached).

**II. DISPUTED CLAIM CONSTRUCTIONS**

With respect to those terms, phrases, or clauses on which the parties could not reach agreement, the parties have set forth their respective proposed constructions, including the intrinsic and extrinsic evidence relied upon in support thereof, in Exhibits B and C (attached). The parties reserve the right to rely on and rebut any evidence cited by any party.

**III. ANTICIPATED LENGTH OF CLAIM CONSTRUCTION HEARING**

The parties believe that it would be appropriate for the Court to allocate two hours for the claim construction hearing, with one hour allocated to each side (including reserved rebuttal time).

**IV. CLAIM CONSTRUCTION LIVE WITNESSES**

The parties do not anticipate calling live witnesses at the claim construction hearing.

**V. CLAIM CONSTRUCTION PREHEARING CONFERENCE**

The parties do not believe a claim construction prehearing conference is needed.

No.	Term	Claim(s)	Plaintiffs' Proposed Construction & Evidentiary Support
			<p><b><u>Extrinsic Support:</u></b></p> <p>“Hashing (or hash coding) is a word coined by computer programmers to describe a general class of operations done to transform one or more fields (usually a key) into a different (usually more compact) arrangement. Probably, “hashing” was first coined because it seemed that “hash” was being made out of integral pieces of data. The rationale for hashing is developed more fully in the article on table lookup, dealing with key transformation to convert naturally occurring, diverse, ill-structured, scattered key fields into compact, easily manipulated fields—usually some numeric, computer oriented field such as a word or double word, or a computer memory address to facilitate subsequent references. The transformation from the natural field to the hash address is only a one-way process, however; the natural field cannot be decoded or reconstructed from the hash. Also, the hashed field may not represent only one unique natural field; many natural fields could hash into the same value.”</p> <p>ENCYCLOPEDIA OF COMPUTER SCIENCE AND ENGINEERING 681 (Anthony Ralston &amp; Edwin D. Reilly, Jr. eds.,1983).</p> <p>“Hashing (1) (* Processing) A technique for converting the values within fields into more ‘compact’ representations of the same values. Usually, the values being converted are keys. (2) (* Addressing) An addressing technique used to store and retrieve data in a file. Hashing uses keys in an index to determine the location of the data in the file.” ROBERT A EDMUND, THE PRENTICE-HALL STANDARD GLOSSARY OF COMPUTER TERMINOLOGY, 191-192 (1985).</p> <p>“Hashing: Hashing refers to a storage mechanism where data items are stored at locations that are determined by a mathematical function of the data. For example, suppose you need to store a list of 100 numbers in memory locations whose addresses run from 1 to 100. One example of a hashing</p>

No.	Term	Claim(s)	Plaintiffs' Proposed Construction & Evidentiary Support
			<p>function is to calculate the remainder when the number is divided by 100 and then store it at that location. For example, the number 538 would be stored at memory location 38. The use of hashing makes it possible to store and retrieve the data items quickly since it is not necessary to search through the list in order to find the item. However, there is one complication: A hashing function will sometimes assign more than one data item to the same address. For example, using the rule given above, the number 638 would also be stored in location 38. To avoid that problem, a hashing system needs to be able to resolve collisions by storing the new data item in a separate place.” DOUGLAS DOWNING &amp; MICHAEL COVINGTON, BARRON’S DICTIONARY OF COMPUTER TERMS 158 (3d ed. 1992).</p> <p>“Hashing: (1) Key-to-address transformation in which the keys determine the location of the data. (2) The process of applying a formula to a record key to yield a number that represents a disk address.” DONALD D. SPENCER, COMPUTER DICTIONARY (3d ed. 1992).</p> <p>“Hashing: In database management, an indexing technique in which the value of a key (record identifier) is numerically manipulated to directly calculate either the location of its associated record in a file or the starting point for a search for the associated record.” MICROSOFT COMPUTER DICTIONARY 193 (2d ed. 1994).</p>
6.	a first portion and a second portion	claims 1, 8, 13	<p><b><u>Construction:</u></b></p> <p>The claim language has its plain and ordinary meaning; no further construction necessary.</p> <p><b><u>Intrinsic Support:</u></b></p>

		<p>class of methods called hashing techniques, based on arithmetic transformations of the actual keys.” Donald Knuth, <i>The Art of Computer Programming, Volume 3, Sorting and Searching</i>, Addison-Wesley, 1973, p. 390.</p> <p>“6.4: Hashing. So far we have considered search methods based on comparing the given argument K to the keys in the table, or using its digits to govern a branching process. A third possibility is to avoid all this rummaging around by doing some arithmetical calculation on K, computing a function <math>f(K)</math> which is the location of K and the associated data on the table. . . . These considerations lead to a popular class of search methods commonly known as hashing or scatter storage techniques. The verb “to hash” means to chop something up or to make a mess out of it; the idea in hashing is to chop off some aspects of the key and to use this partial information as the basis for searching. We compute a hash function <math>h(K)</math> and use this value as the address where the search begins.” Donald Knuth, <i>The Art of Computer Programming, Volume 3, Sorting and Searching</i>, Addison-Wesley, 1973, p. 506-07.</p> <p>“Prototype Specifications . . . The hash algorithm is taken from Knuth, volume 3, section 6.4.” (JAR 219469)</p> <p>“hash: An associative access technique that maps the key via a hash function uniformly among a partitioned set of hash buckets. A key search consists of hashing the key to a bucket address and then examining the small hash bucket for records with the desired key.” Jim Gray, Andreas Reuter, <i>Transaction Processing: Concepts and Techniques</i>, Morgan Kaufman, 1993, p. 120; <i>see also generally</i> pp. 831-851.</p> <p>“Associative access on a single relation can be supported by two types of access paths that use fundamentally different approaches to solving the problem of translating attribute values into tuple addresses. These approaches, which yield fundamentally different functionality, are generally referred to as hashing</p>

		<p>(key transformation) and key comparison.” Jim Gray, Andreas Reuter, <i>Transaction Processing: Concepts and Techniques</i>, Morgan Kaufman, 1993, p. 833.</p> <p>“Hashing is based on the idea of using the primary key value as a parameter to a function which returns the storage location of the tuple as a result. This is the very principle of hashing, and it has a number of interesting properties. If the transformation function can be kept simple—that is, if it does not need large data structures with search paths and routing data—then the access cost to retrieve a tuple via its key is minimal: take the key value, do some arithmetic, and find the tuple at the address delivered by the function. Ideal hash algorithms allow for one-access retrieval, which is to say that only the page holding the tuple needs to be read when accessing via the primary key. The functional principle of simple hashing is to relate to key value of a tuple and the page number in which it is stored, through a predefined function; because of this, simple hashing is not just an access method, but also a file organization technique. (This was explained in Chapter 14.) As such, it needs page address spaces with special properties, as with become obvious during the detailed description. Hash-based access paths support only queries of the type (key-attribute = const). They do not efficiently support range predicates such as key-attribute between A and B. The attribute used for hashing typically is a primary key of the relation, but can also be used for nonunique attributes.” Jim Gray, Andreas Reuter, <i>Transaction Processing: Concepts and Techniques</i>, Morgan Kaufman, 1993, p. 833.</p> <p>“Key comparison comprises all methods for maintaining a dynamic search structure on the set of values in the key attribute. These values (or compressed versions of them) can be organized into tables, lists, trees, and so on, depending on the amount of data, the type of search operations to be supported, and the storage size that is available for maintaining the search structure. If such a technique is used for a primary access path, the entire tuple can be stored in</p>

		<p>search structure (see Section 14.4.5, on key-sequenced files, in Chapter 14); otherwise, it will contain pointers to the tuples (e.g., TIDs). Sorting a file along some attribute and keeping it sorted under updates is a very simple example of a search structure based on key comparison—in this case, it is a sequential sorted list of tuples. If records are clustered within blocks according to the key attribute values, searching and scanning in sorted order can be performed efficiently.” Jim Gray, Andreas Reuter, <i>Transaction Processing: Concepts and Techniques</i>, Morgan Kaufman, 1993, p. 833.</p> <p>“Algorithms to implement associative access come in two flavors. The first one, hashing, supports access based on value equality only; it uses a transformation function that turns the attribute value into a page address where the tuple can be found.” Jim Gray, Andreas Reuter, <i>Transaction Processing: Concepts and Techniques</i>, Morgan Kaufman, 1993, p. 835.</p> <p>“As in hash-based memory organizations, there has to be a function to transform the attribute value into a file address, where the tuple will (most likely) be found.” Jim Gray, Andreas Reuter, <i>Transaction Processing: Concepts and Techniques</i>, Morgan Kaufman, 1993, p. 835.</p> <p>“[A] good hash function <math>H</math> has to map primary key values, which are very unevenly distributed over a large value range, into a tuple address space that is much smaller (proportional to the number of existing tuples), such that the resulting addresses are evenly distributed over the address range.” Jim Gray, Andreas Reuter, <i>Transaction Processing: Concepts and Techniques</i>, Morgan Kaufman, 1993, p. 839.</p> <p>“[i]f the hash function <math>h(p)</math> is properly chosen, then the hash values will be approximately uniformly distributed over their range.” (JAR 108483)</p> <p>Kenneth Baclawski and J. A hashing algorithm is used with a random file to determine the address of the block in which a given record should be stored.” Gunton, Tony, <i>A Dictionary of Information Technology and Computer Science</i> (2nd ed.) (Oxford, UK: NCC Blackwell Ltd.), 1993, p. 136. (GN 292980)</p> <p>“Section 6.3 treats digital searching, and Section 6.4 discusses an important class of methods called hashing techniques, based on arithmetic transformations of the actual keys.” Donald Knuth, <i>The Art of Computer Programming, Volume 3, Sorting and Searching</i>, Addison-Wesley, 1973, p. 390.</p> <p>“6.4: Hashing. So far we have considered search methods based on comparing the given argument K to the keys in the table, or using its digits to govern a branching process. A third possibility is to avoid all this rummaging around by doing some arithmetical calculation on K, computing a function f(K) which is the location of K and the associated data on the table. . . . These considerations lead to a popular class of search methods commonly known as hashing or scatter storage techniques. The verb “to hash” means to chop something up or to make a mess out of it; the idea in hashing is to chop off some aspects of the</p>

		<p>key and to use this partial information as the basis for searching. We compute a hash function <math>h(K)</math> and use this value as the address where the search begins.” Donald Knuth, <i>The Art of Computer Programming, Volume 3, Sorting and Searching</i>, Addison-Wesley, 1973, p. 506-07.</p> <p>“Prototype Specifications . . . The hash algorithm is taken from Knuth, volume 3, section 6.4.” (JAR 219469)</p> <p>“hash: An associative access technique that maps the key via a hash function uniformly among a partitioned set of hash buckets. A key search consists of hashing the key to a bucket address and then examining the small hash bucket for records with the desired key.” Jim Gray, Andreas Reuter, <i>Transaction Processing: Concepts and Techniques</i>, Morgan Kaufman, 1993, p. 120; <i>see also generally</i> pp. 831-851.</p> <p>“Associative access on a single relation can be supported by two types of access paths that use fundamentally different approaches to solving the problem of translating attribute values into tuple addresses. These approaches, which yield fundamentally different functionality, are generally referred to as hashing (key transformation) and key comparison.” Jim Gray, Andreas Reuter, <i>Transaction Processing: Concepts and Techniques</i>, Morgan Kaufman, 1993, p. 833.</p> <p>“Hashing is based on the idea of using the primary key value as a parameter to a function which returns the storage location of the tuple as a result. This is the very principle of hashing, and it has a number of interesting properties. If the transformation function can be kept simple—that is, if it does not need large data structures with search paths and routing data—then the access cost to retrieve a tuple via its key is minimal: take the key value, do some arithmetic, and find the tuple at the address delivered by the function. Ideal hash algorithms allow for one-access retrieval, which is to say that only the page</p>

		<p>holding the tuple needs to be read when accessing via the primary key. The functional principle of simple hashing is to relate to key value of a tuple and the page number in which it is stored, through a predefined function; because of this, simple hashing is not just an access method, but also a file organization technique. (This was explained in Chapter 14.) As such, it needs page address spaces with special properties, as with become obvious during the detailed description. Hash-based access paths support only queries of the type (key-attribute = const). They do not efficiently support range predicates such as key-attribute between A and B. The attribute used for hashing typically is a primary key of the relation, but can also be used for nonunique attributes.” Jim Gray, Andreas Reuter, <i>Transaction Processing: Concepts and Techniques</i>, Morgan Kaufman, 1993, p. 833.</p> <p>“Key comparison comprises all methods for maintaining a dynamic search structure on the set of values in the key attribute. These values (or compressed versions of them) can be organized into tables, lists, trees, and so on, depending on the amount of data, the type of search operations to be supported, and the storage size that is available for maintaining the search structure. If such a technique is used for a primary access path, the entire tuple can be stored in search structure (see Section 14.4.5, on key-sequenced files, in Chapter 14); otherwise, it will contain pointers to the tuples (e.g., TIDs). Sorting a file along some attribute and keeping it sorted under updates is a very simple example of a search structure based on key comparison—in this case, it is a sequential sorted list of tuples. If records are clustered within blocks according to the key attribute values, searching and scanning in sorted order can be performed efficiently.” Jim Gray, Andreas Reuter, <i>Transaction Processing: Concepts and Techniques</i>, Morgan Kaufman, 1993, p. 833.</p> <p>“Algorithms to implement associative access come in two flavors. The first one, hashing, supports access based on value equality only; it uses a transformation function that turns the attribute value into a page address where</p>
